CogDL is a graph representation learning toolkit that allows researchers and developers to easily train and compare baseline or custom models for node classification, link prediction and other tasks on graphs. It provides implementations of many popular models, including: non-GNN Baselines like Deepwalk, LINE, NetMF, GNN Baselines like GCN, GAT, GraphSAGE.

CogDL provides these features:

- Task-Oriented: CogDL focuses on tasks on graphs and provides corresponding models, datasets, and leaderboards.
- Easy-Running: CogDL supports running multiple experiments simultaneously on multiple models and datasets under a specific task using multiple GPUs.
- Multiple Tasks: CogDL supports node classification and link prediction tasks on homogeneous/heterogeneous networks, as well as graph classification.
- Extensibility: You can easily add new datasets, models and tasks and conduct experiments for them!
- Supported tasks:
  - Node classification
  - Link prediction
  - Graph classification
  - Community detection (testing)
  - Social influence prediction (testing)
  - Graph reasoning (todo)
  - Graph pre-training (todo)
  - Combinatorial optimization on graphs (todo)

CHAPTER

ONE

INSTALL

- PyTorch version >= 1.0.0
- Python version >= 3.6
- PyTorch Geometric (optional)

Please follow the instructions here to install PyTorch: https://github.com/pytorch/pytorch#installation.

Please follow the instructions here to install PyTorch Geometric: https://github.com/rusty1s/pytorch_geometric/#installation.

Install other dependencies:

```
>>> pip install -e .
```

CHAPTER

TWO

TUTORIAL

This guide can help you start working with CogDL.

2.1 Create a model

Here, we will create a spectral clustering model, which is a very simple graph embedding algorithm. We name it spectral.py and put it in cogdl/models/emb directory.

First we import necessary library like numpy, scipy, networkx, sklearn, we also import API like 'BaseModel' and 'register_model' from cogl/models/ to build our new model:

```
import numpy as np
import networkx as nx
import scipy.sparse as sp
from sklearn import preprocessing
from .. import BaseModel, register_model
```

Then we use function decorator to declare new model for CogDL

```
@register_model('spectral')
class Spectral(BaseModel):
    (...)
```

We have to implement method 'build_model_from_args' in spectral.py. If it need more parameters to train, we can use 'add_args' to add model-specific arguments.

```
@staticmethod
def add_args(parser):
    """Add model-specific arguments to the parser."""
    pass

@classmethod
def build_model_from_args(cls, args):
    return cls(args.hidden_size)

def __init__(self, dimension):
    super(Spectral, self).__init__()
    self.dimension = dimension
```

Each new model should provide a 'train' method to obtain representation.

```
def train(self, G):
    matrix = nx.normalized_laplacian_matrix(G).todense()
    matrix = np.eye(matrix.shape[0]) - np.asarray(matrix)
    ut, s, _ = sp.linalg.svds(matrix, self.dimension)
    emb_matrix = ut * np.sqrt(s)
    emb_matrix = preprocessing.normalize(emb_matrix, "l2")
    return emb_matrix
```

2.2 Create a dataset

In order to add a dataset into CogDL, you should know your dataset's format. We have provided several graph format like edgelist, matlab_matrix and pyg. If your dataset is same as the 'ppi' dataset, which contains two matrices: 'network' and 'group', you can register your dataset directly use above code.

```
@register_dataset("ppi")
class PPIDataset(MatlabMatrix):
    def __init__(self):
        dataset, filename = "ppi", "Homo_sapiens"
        url = "http://snap.stanford.edu/node2vec/"
        path = osp.join(osp.dirname(osp.realpath(__file__)), "../..", "data", dataset)
        super(PPIDataset, self).__init__(path, filename, url)
```

You should declare the name of the dataset, the name of file and the url, where our script can download resource.

2.3 Create a task

In order to evaluate some methods on several datasets, we can build a task and evaluate learned representation. The BaseTask class are:

```
class BaseTask(object):
    @staticmethod
    def add_args(parser):
        """Add task-specific arguments to the parser."""
        pass

    def __init__(self, args):
        pass

    def train(self, num_epoch):
        raise NotImplementedError
```

we can create a subclass to implement 'train' method like CommunityDetection, which get representation of each node and apply clustering algorithm(K-means) to evaluate.

```
@register_task("community_detection")
class CommunityDetection(BaseTask):
    """Community Detection task."""

    @staticmethod
    def add_args(parser):
        """Add task-specific arguments to the parser."""
        parser.add_argument("--hidden-size", type=int, default=128)
```

(continues on next page)

(continued from previous page)

```
        parser.add_argument("--num-shuffle", type=int, default=5)

    def __init__(self, args):
        super(CommunityDetection, self).__init__(args)
        dataset = build_dataset(args)
        self.data = dataset[0]

        self.num_nodes, self.num_classes = self.data.y.shape
        self.label = np.argmax(self.data.y, axis=1)
        self.model = build_model(args)
        self.hidden_size = args.hidden_size
        self.num_shuffle = args.num_shuffle

    def train(self):
        G = nx.Graph()
        G.add_edges_from(self.data.edge_index.t().tolist())
        embeddings = self.model.train(G)

        clusters = [30, 50, 70]
        all_results = defaultdict(list)
        for num_cluster in clusters:
            for _ in range(self.num_shuffle):
                model = KMeans(n_clusters=num_cluster).fit(embeddings)
                nmi_score = normalized_mutual_info_score(self.label, model.labels_)
                all_results[num_cluster].append(nmi_score)

        return dict(
            (
                f"normalized_mutual_info_score {num_cluster}",
                sum(all_results[num_cluster]) / len(all_results[num_cluster]),
            )
            for num_cluster in sorted(all_results.keys())
        )
```

2.4 Combine model, dataset and task

After create your model, dataset and task, we could combine them together to learn representation from a model on a dataset and evaluate its performance according to a task. We use 'build_model', 'build_dataset', 'build_task' method to build them with cooresponding parameters.

```
from cogdl.tasks import build_task
from cogdl.datasets import build_dataset
from cogdl.models import build_model
from cogdl.utils import build_args_from_dict

def test_deepwalk_ppi():
    default_dict = {'hidden_size': 64, 'num_shuffle': 1, 'cpu': True}
    args = build_args_from_dict(default_dict)

    # model, dataset and task parameters
    args.model = 'spectral'
    args.dataset = 'ppi'
    args.task = 'community_detection'
```

(continues on next page)

(continued from previous page)

```
    # build model, dataset and task
    dataset = build_dataset(args)
    model = build_model(args)
    task = build_task(args)

    # train model and get evaluate results
    ret = task.train()
    print(ret)
```

CHAPTER

THREE

TASKS

3.1 Node Classification

In this tutorial, we will introduce a important task, node classification. In this task, we train a GNN model with partial node labels and use accuracy to measure the performance.

First we define the *NodeClassification* class.

```
@register_task("node_classification")
class NodeClassification(BaseTask):
    """Node classification task."""

    @staticmethod
    def add_args(parser):
        """Add task-specific arguments to the parser."""

    def __init__(self, args):
        super(NodeClassification, self).__init__(args)
```

Then we can build dataset according to args.

```
self.device = torch.device('cpu' if args.cpu else 'cuda')
dataset = build_dataset(args)
self.data = dataset.data
self.data.apply(lambda x: x.to(self.device))
args.num_features = dataset.num_features
args.num_classes = dataset.num_classes
```

After that, we can build model and use *Adam* to optimize the model.

```
model = build_model(args)
self.model = model.to(self.device)
self.patience = args.patience
self.max_epoch = args.max_epoch
self.optimizer = torch.optim.Adam(
    self.model.parameters(), lr=args.lr, weight_decay=args.weight_decay
)
```

We provide a training loop for node classification task. For each epoch, we first call *_train_step* to optimize our model and then call *_test_step* to compute the accuracy and loss.

```
def train(self):
    epoch_iter = tqdm(range(self.max_epoch))
    patience = 0
```

(continues on next page)

(continued from previous page)

```
    best_score = 0
    best_loss = np.inf
    max_score = 0
    min_loss = np.inf
    for epoch in epoch_iter:
        self._train_step()
        train_acc, _ = self._test_step(split="train")
        val_acc, val_loss = self._test_step(split="val")
        epoch_iter.set_description(
            f"Epoch: {epoch:03d}, Train: {train_acc:.4f}, Val: {val_acc:.4f}"
        )
        if val_loss <= min_loss or val_acc >= max_score:
            if val_loss <= best_loss:  # and val_acc >= best_score:
                best_loss = val_loss
                best_score = val_acc
                best_model = copy.deepcopy(self.model)
            min_loss = np.min((min_loss, val_loss))
            max_score = np.max((max_score, val_acc))
            patience = 0
        else:
            patience += 1
            if patience == self.patience:
                self.model = best_model
                epoch_iter.close()
                break

def _train_step(self):
    self.model.train()
    self.optimizer.zero_grad()
    self.model.loss(self.data).backward()
    self.optimizer.step()

def _test_step(self, split="val"):
    self.model.eval()
    logits = self.model.predict(self.data)
    _, mask = list(self.data(f"{split}_mask"))[0]
    loss = F.nll_loss(logits[mask], self.data.y[mask])

    pred = logits[mask].max(1)[1]
    acc = pred.eq(self.data.y[mask]).sum().item() / mask.sum().item()
    return acc, loss
```

Finally, we compute the accuracy scores of test set for the trained model.

```
test_acc, _ = self._test_step(split="test")
print(f"Test accuracy = {test_acc}")
return dict(Acc=test_acc)
```

The overall implementation of *NodeClassification* is at (https://github.com/THUDM/cogdl/blob/master/cogdl/tasks/node_classification.py).

To run NodeClassification, we can use the following command:

```
python scripts/train.py --task node_classification --dataset cora citeseer --model␣
↪pyg_gcn pyg_gat --seed 0 1 --max-epoch 500
```

Then We get experimental results like this:

Variant	Acc
('cora', 'pyg_gcn')	0.7785±0.0165
('cora', 'pyg_gat')	0.7925±0.0045
('citeseer', 'pyg_gcn')	0.6535±0.0195
('citeseer', 'pyg_gat')	0.6675±0.0025

3.2 Unsupervised Node Classification

In this tutorial, we will introduce a important task, unsupervised node classification. In this task, we usually apply L2 normalized logisitic regression to train a classifier and use F1-score to measure the performance.

First we define the *UnsupervisedNodeClassification* class, which has two parameters *hidden-size* and *num-shuffle* . *hidden-size* represents the dimension of node representation, while *num-shuffle* means the shuffle times in classifier.

```
@register_task("unsupervised_node_classification")
class UnsupervisedNodeClassification(BaseTask):
    """Node classification task."""

    @staticmethod
    def add_args(parser):
        """Add task-specific arguments to the parser."""
        # fmt: off
        parser.add_argument("--hidden-size", type=int, default=128)
        parser.add_argument("--num-shuffle", type=int, default=5)
        # fmt: on

    def __init__(self, args):
        super(UnsupervisedNodeClassification, self).__init__(args)
```

Then we can build dataset according to input graph's type, and get *self.label_matrix*.

```
dataset = build_dataset(args)
self.data = dataset[0]
if issubclass(dataset.__class__.__bases__[0], InMemoryDataset):
    self.num_nodes = self.data.y.shape[0]
    self.num_classes = dataset.num_classes
    self.label_matrix = np.zeros((self.num_nodes, self.num_classes), dtype=int)
    self.label_matrix[range(self.num_nodes), self.data.y] = 1
    self.data.edge_attr = self.data.edge_attr.t()
else:
    self.label_matrix = self.data.y
    self.num_nodes, self.num_classes = self.data.y.shape
```

After that, we can build model and run *model.train(G)* to obtain node representation.

```
self.model = build_model(args)
self.model_name = args.model
self.hidden_size = args.hidden_size
self.num_shuffle = args.num_shuffle
self.save_dir = args.save_dir
self.enhance = args.enhance
self.args = args
self.is_weighted = self.data.edge_attr is not None
```

(continues on next page)

(continued from previous page)

```
def train(self):
    G = nx.Graph()
    if self.is_weighted:
        edges, weight = (
            self.data.edge_index.t().tolist(),
            self.data.edge_attr.tolist(),
        )
        G.add_weighted_edges_from(
            [(edges[i][0], edges[i][1], weight[0][i]) for i in range(len(edges))]
        )
    else:
        G.add_edges_from(self.data.edge_index.t().tolist())
    embeddings = self.model.train(G)
```

The spectral propagation in ProNE can improve the quality of representation learned from other methods, so we can use *enhance_emb* to enhance performance.

```
    if self.enhance is True:
        embeddings = self.enhance_emb(G, embeddings)

def enhance_emb(self, G, embs):
    A = sp.csr_matrix(nx.adjacency_matrix(G))
    self.args.model = 'prone'
    self.args.step, self.args.theta, self.args.mu = 5, 0.5, 0.2
    model = build_model(self.args)
    embs = model._chebyshev_gaussian(A, embs)
    return embs
```

When the embeddings are obtained, we can save them at *self.save_dir*.

```
# Map node2id
    features_matrix = np.zeros((self.num_nodes, self.hidden_size))
    for vid, node in enumerate(G.nodes()):
        features_matrix[node] = embeddings[vid]

self.save_emb(features_matrix)

def save_emb(self, embs):
    name = os.path.join(self.save_dir, self.model_name + '_emb.npy')
    np.save(name, embs)
```

At last, we evaluate embedding via run *num_shuffle* times classification under different training ratio with *features_matrix* and *label_matrix*.

```
return self._evaluate(features_matrix, label_matrix, self.num_shuffle)

    def _evaluate(self, features_matrix, label_matrix, num_shuffle):
        # shuffle, to create train/test groups
        shuffles = []
        for _ in range(num_shuffle):
            shuffles.append(skshuffle(features_matrix, label_matrix))

        # score each train/test group
        all_results = defaultdict(list)
        training_percents = [0.1, 0.3, 0.5, 0.7, 0.9]
```

(continues on next page)

(continued from previous page)

```
        for train_percent in training_percents:
            for shuf in shuffles:
```

In each shuffle, split data into two parts(training and testing) and use *LogisticRegression* to evaluate.

```
X, y = shuf

training_size = int(train_percent * self.num_nodes)

X_train = X[:training_size, :]
y_train = y[:training_size, :]

X_test = X[training_size:, :]
y_test = y[training_size:, :]

clf = TopKRanker(LogisticRegression())
clf.fit(X_train, y_train)

# find out how many labels should be predicted
top_k_list = list(map(int, y_test.sum(axis=1).T.tolist()[0]))
preds = clf.predict(X_test, top_k_list)
result = f1_score(y_test, preds, average="micro")
all_results[train_percent].append(result)
```

Node in graph may have multiple labels, so we conduct multilbel classification built from TopKRanker.

```
from sklearn.multiclass import OneVsRestClassifier

class TopKRanker(OneVsRestClassifier):
    def predict(self, X, top_k_list):
        assert X.shape[0] == len(top_k_list)
        probs = np.asarray(super(TopKRanker, self).predict_proba(X))
        all_labels = sp.lil_matrix(probs.shape)

        for i, k in enumerate(top_k_list):
            probs_ = probs[i, :]
            labels = self.classes_[probs_.argsort()[-k:]].tolist()
            for label in labels:
                all_labels[i, label] = 1
        return all_labels
```

Finally, we get the results of Micro-F1 score under different training ratio for different models on datasets.

```
return dict(
    (
        f"Micro-F1 {train_percent}",
        sum(all_results[train_percent]) / len(all_results[train_percent]),
    )
    for train_percent in sorted(all_results.keys())
)
```

The overall implementation of *UnsupervisedNodeClassification* is at (https://github.com/THUDM/cogdl/blob/master/cogdl/tasks/unsupervised_node_classification.py).

To run UnsupervisedNodeClassification, we can use following instruction:

```
python scripts/train.py --task unsupervised_node_classification --dataset ppi␣
↪wikipedia --model deepwalk prone -seed 0 1
```

Then We get experimental results like this:

Variant	Micro-F1 0.1	Micro-F1 0.3	Micro-F1 0.5	Micro-F1 0.7	Micro-F1 0.9
('ppi', 'deepwalk')	0.1547±0.0002	0.1846±0.0002	0.2033±0.0015	0.2161±0.0009	0.2243±0.0018
('ppi', 'prone')	0.1777±0.0016	0.2214±0.0020	0.2397±0.0015	0.2486±0.0022	0.2607±0.0096
('wikipedia', 'deepwalk')	0.4255±0.0027	0.4712±0.0005	0.4916±0.0011	0.5011±0.0017	0.5166±0.0043
('wikipedia', 'prone')	0.4834±0.0009	0.5320±0.0020	0.5504±0.0045	0.5586±0.0022	0.5686±0.0072

3.3 Supervised Graph Classification

In this section, we will introduce the implementation "Graph classification task".

Task Design

1. Set up "SupervisedGraphClassification" class, which has two specific parameters.
    - *degree-feature*: Use one-hot node degree as node feature, for datasets such as lmdb-binary and lmdb-multi, which don't have node features.
    - *gamma*: Multiplicative factor of learning rate decay.
    - *lr*: Learning rate.
2. Build dataset convert it to a list of *Data* defined in Cogdl. Specially, we reformat the data according to the input format of specific models. *generate_data* is implemented to convert dataset.

```
dataset = build_dataset(args)
self.data = self.generate_data(dataset, args)

def generate_data(self, dataset, args):
     if "ModelNet" in str(type(dataset).__name__):
         train_set, test_set = dataset.get_all()
         args.num_features = 3
         return {"train": train_set, "test": test_set}
    else:
        datalist = []
        if isinstance(dataset[0], Data):
            return dataset
        for idata in dataset:
            data = Data()
            for key in idata.keys:
                data[key] = idata[key]
                datalist.append(data)

        if args.degree_feature:
            datalist = node_degree_as_feature(datalist)
            args.num_features = datalist[0].num_features
        return datalist
```

3. Then we build model and can run *train* to train the model.

```
def train(self):
    for epoch in epoch_iter:
         self._train_step()
         val_acc, val_loss = self._test_step(split="valid")
         # ...
         return dict(Acc=test_acc)

def _train_step(self):
    self.model.train()
    loss_n = 0
    for batch in self.train_loader:
        batch = batch.to(self.device)
        self.optimizer.zero_grad()
        output, loss = self.model(batch)
        loss_n += loss.item()
        loss.backward()
        self.optimizer.step()

def _test_step(self, split):
    """split in ['train', 'test', 'valid']"""
    # ...
    return acc, loss
```

The overall implementation of GraphClassification is at (https://github.com/THUDM/cogdl/blob/master/cogdl/tasks/graph_classification.py).

Create a model

To create a model for task graph classification, the following functions have to be implemented.

1. *add_args(parser)*: add necessary hyper-parameters used in model.

```
@staticmethod
def add_args(parser):
     parser.add_argument("--hidden-size", type=int, default=128)
     parser.add_argument("--num-layers", type=int, default=2)
     parser.add_argument("--lr", type=float, default=0.001)
     # ...
```

2. *build_model_from_args(cls, args)*: this function is called in 'task' to build model.
3. *split_dataset(cls, dataset, args)*: split train/validation/test data and return correspondent dataloader according to requirement of model.

```
def split_dataset(cls, dataset, args):
    random.shuffle(dataset)
    train_size = int(len(dataset) * args.train_ratio)
    test_size = int(len(dataset) * args.test_ratio)
    bs = args.batch_size
    train_loader = DataLoader(dataset[:train_size], batch_size=bs)
    test_loader = DataLoader(dataset[-test_size:], batch_size=bs)
    if args.train_ratio + args.test_ratio < 1:
         valid_loader = DataLoader(dataset[train_size:-test_size], batch_size=bs)
    else:
         valid_loader = test_loader
    return train_loader, valid_loader, test_loader
```

4. *forward*: forward propagation, and the return should be (predication, loss) or (prediction, None), respectively for training and test. Input parameters of *forward* is class *Batch*, which

```
def forward(self, batch):
 h = batch.x
 layer_rep = [h]
 for i in range(self.num_layers-1):
     h = self.gin_layers[i](h, batch.edge_index)
     h = self.batch_norm[i](h)
     h = F.relu(h)
     layer_rep.append(h)

 final_score = 0
 for i in range(self.num_layers):
 pooled = scatter_add(layer_rep[i], batch.batch, dim=0)
 final_score += self.dropout(self.linear_prediction[i](pooled))
 final_score = F.softmax(final_score, dim=-1)
 if batch.y is not None:
     loss = self.loss(final_score, batch.y)
     return final_score, loss
 return final_score, None
```

Run

To run GraphClassification, we can use the following command:

```
python scripts/train.py --task graph_classification --dataset proteins --model gin␣
↪diffpool sortpool dgcnn --seed 0 1
```

Then We get experimental results like this:

Variants	Acc
('proteins', 'gin')	0.7286±0.0598
('proteins', 'diffpool')	0.7530±0.0589
('proteins', 'sortpool')	0.7411±0.0269
('proteins', 'dgcnn')	0.6677±0.0355
('proteins', 'patchy_san')	0.7550±0.0812

3.4 Unsupervised Graph Classification

In this section, we will introduce the implementation "Unsupervised graph classification task".

Task Design

1. Set up "UnsupervisedGraphClassification" class, which has two specific parameters.
    - *num-shuffle* : Shuffle times in classifier
    - *degree-feature*: Use one-hot node degree as node feature, for datasets such as lmdb-binary and lmdb-multi, which don't have node features.
    - *lr*: learning

```
@register_task("unsupervised_graph_classification")
class UnsupervisedGraphClassification(BaseTask):
    r"""Unsupervised graph classification"""
    @staticmethod
    def add_args(parser):
        """Add task-specific arguments to the parser."""
```

(continues on next page)

(continued from previous page)

```
        # fmt: off
        parser.add_argument("--num-shuffle", type=int, default=10)
        parser.add_argument("--degree-feature", dest="degree_feature", action="store_
↪true")
        parser.add_argument("--lr", type=float, default=0.001)
        # fmt: on
    def __init__(self, args):
        # ...
```

2. Build dataset and convert it to a list of *Data* defined in Cogdl.

```
dataset = build_dataset(args)
self.label = np.array([data.y for data in dataset])
self.data = [
     Data(x=data.x, y=data.y, edge_index=data.edge_index, edge_attr=data.edge_attr,
             pos=data.pos).apply(lambda x:x.to(self.device))
             for data in dataset
]
```

3. Then we build model and can run *train* to train the model and obtain graph representation. In this part, the training process of shallow models and deep models are implemented separately.

```
self.model = build_model(args)
self.model = self.model.to(self.device)

def train(self):
     if self.use_nn:
         # deep neural network models
              epoch_iter = tqdm(range(self.epoch))
         for epoch in epoch_iter:
             loss_n = 0
             for batch in self.data_loader:
                 batch = batch.to(self.device)
                 predict, loss = self.model(batch.x, batch.edge_index, batch.batch)
              self.optimizer.zero_grad()
              loss.backward()
              self.optimizer.step()
              loss_n += loss.item()
     # ...
     else:
        # shallow models
         prediction, loss = self.model(self.data)
         label = self.label
```

4. When graph representation is obtained, we evaluate the embedding with *SVM* via running *num_shuffle* times under different training ratio. You can also call *save_emb* to save the embedding.

```
return self._evaluate(prediction, label)
def _evaluate(self, embedding, labels):
    # ...
    for training_percent in training_percents:
         for shuf in shuffles:
             # ...
             clf = SVC()
             clf.fit(X_train, y_train)
             preds = clf.predict(X_test)
```

(continues on next page)

(continued from previous page)

```
            # ...
```

The overall implementation of UnsupervisedGraphClassification is at (https://github.com/THUDM/cogdl/blob/master/cogdl/tasks/unsupervised_graph_classification.py).

Create a model

To create a model for task unsupervised graph classification, the following functions have to be implemented.

1. *add_args(parser)*: add necessary hyper-parameters used in model.

```
@staticmethod
def add_args(parser):
  parser.add_argument("--hidden-size", type=int, default=128)
  parser.add_argument("--nn", type=bool, default=False)
  parser.add_argument("--lr", type=float, default=0.001)
  # ...
```

2. *build_model_from_args(cls, args)*: this function is called in 'task' to build model.
3. *forward*: For shallow models, this function runs as training process of model and will be called only once; For deep neural network models, this function is actually the forward propagation process and will be called many times.

```
# shallow model
def forward(self, graphs):
     # ...
    self.model = Doc2Vec(
        self.doc_collections,
             ...
    )
    vectors = np.array([self.model["g_"+str(i)] for i in range(len(graphs))])
    return vectors, None
```

Run

To run UnsupervisedGraphClassification, we can use the following command:

```
python scripts/train.py --task unsupervised_graph_classification --dataset proteins --
↪model dgk graph2vec
```

Then we get experimental results like this:

Variant	Acc
('proteins', 'dgk')	0.7259±0.0118
('proteins', 'graph2vec')	0.7330±0.0043
('proteins', 'infograph')	0.7393±0.0070

data.batch

Module Contents

Classes

Batch	A plain old python object modeling a batch of graphs as one big

class data.batch.**Batch**(*batch=None*, ***kwargs*)

Bases: cogdl.data.Data

A plain old python object modeling a batch of graphs as one big (dicconnected) graph. With cogdl.data.Data being the base class, all its methods can also be used here. In addition, single graphs can be reconstructed via the assignment vector batch, which maps each node to its respective graph identifier.

static from_data_list(*data_list*, *follow_batch=[]*)

Constructs a batch object from a python list holding torch_geometric.data.Data objects. The assignment vector batch is created on the fly. Additionally, creates assignment batch vectors for each key in follow_batch.

cumsum(*self*, *key*, *item*)

If True, the attribute key with content item should be added up cumulatively before concatenated together.

> **Note:** This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

to_data_list(*self*)

Reconstructs the list of torch_geometric.data.Data objects from the batch object. The batch object must have been created via *from_data_list()* in order to be able reconstruct the initial objects.

property num_graphs(*self*)

Returns the number of graphs in the batch.

data.data

Module Contents

Classes

Data	A plain old python object modeling a single graph with various

class data.data.**Data**(*x=None*, *edge_index=None*, *edge_attr=None*, *y=None*, *pos=None*)

Bases: object

A plain old python object modeling a single graph with various (optional) attributes:

Args:

**x (Tensor, optional): Node feature matrix with shape :obj:`[num_nodes,** num_node_features]`. (default: `None`)

edge_index (LongTensor, optional): Graph connectivity in COO format with shape `[2, num_edges]`. (default: `None`)

edge_attr (Tensor, optional): Edge feature matrix with shape `[num_edges, num_edge_features]`. (default: `None`)

y (Tensor, optional): Graph or node targets with arbitrary shape. (default: `None`)

pos (Tensor, optional): Node position matrix with shape `[num_nodes, num_dimensions]`. (default: `None`)

The data object is not restricted to these attributes and can be extented by any other additional data.

static from_dict(*dictionary*)
Creates a data object from a python dictionary.

__getitem__(*self*, *key*)
Gets the data of the attribute `key`.

__setitem__(*self*, *key*, *value*)
Sets the attribute `key` to `value`.

property keys(*self*)
Returns all names of graph attributes.

__len__(*self*)
Returns the number of all present attributes.

__contains__(*self*, *key*)
Returns `True`, if the attribute `key` is present in the data.

__iter__(*self*)
Iterates over all present attributes in the data, yielding their attribute names and content.

__call__(*self*, **keys*)
Iterates over all attributes `*keys` in the data, yielding their attribute names and content. If `*keys` is not given this method will iterative over all present attributes.

cat_dim(*self*, *key*, *value*)
Returns the dimension in which the attribute `key` with content `value` gets concatenated when creating batches.

Note: This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

__inc__(*self*, *key*, *value*)
"Returns the incremental count to cumulatively increase the value of the next attribute of `key` when creating batches.

Note: This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

---

property num_edges (*self*)
Returns the number of edges in the graph.

property num_features (*self*)
Returns the number of features per node in the graph.

property num_nodes (*self*)

is_coalesced (*self*)
Returns `True`, if edge indices are ordered and do not contain duplicate entries.

apply (*self*, *func*, **keys*)
Applies the function `func` to all attributes `*keys`. If `*keys` is not given, `func` is applied to all present attributes.

contiguous (*self*, **keys*)
Ensures a contiguous memory layout for all attributes `*keys`. If `*keys` is not given, all present attributes are ensured to have a contiguous memory layout.

to (*self*, *device*, **keys*)
Performs tensor dtype and/or device conversion to all attributes `*keys`. If `*keys` is not given, the conversion is applied to all present attributes.

cuda (*self*, **keys*)

clone (*self*)

__repr__ (*self*)
Return repr(self).

data.dataloader

Module Contents

Classes

DataLoader	Data loader which merges data objects from a
DataListLoader	Data loader which merges data objects from a
DenseDataLoader	Data loader which merges data objects from a

class data.dataloader.**DataLoader** (*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a mini-batch.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

class data.dataloader.**DataListLoader** (*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a python list.

Note: This data loader should be used for multi-gpu support via `cogdl.nn.DataParallel`.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

class data.dataloader.**DenseDataLoader**(*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a mini-batch.

Note: To make use of this data loader, all graphs in the dataset needs to have the same shape for each its attributes. Therefore, this data loader should only be used when working with *dense* adjacency matrices.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

data.dataset

Module Contents

Classes

Dataset	Dataset base class for creating graph datasets.

Functions

to_list(x)

files_exist(files)

data.dataset.**to_list**(*x*)

data.dataset.**files_exist**(*files*)

class data.dataset.**Dataset**(*root*, *transform=None*, *pre_transform=None*, *pre_filter=None*)
Bases: `torch.utils.data.Dataset`

Dataset base class for creating graph datasets. See here for the accompanying tutorial.

Args: root (string): Root directory where the dataset should be saved. transform (callable, optional): A func-

tion/transform that takes in an

`cogdl.data.Data` object and returns a transformed version. The data object will be transformed before every access. (default: `None`)

pre_transform (callable, optional): A function/transform that takes in an `cogdl.data.Data` object and returns a transformed version. The data object will be transformed before being saved to disk. (default: `None`)

pre_filter (callable, optional): A function that takes in an `cogdl.data.Data` object and returns a boolean value, indicating whether the data object should be included in the final dataset. (default: `None`)

property raw_file_names(*self*)
The name of the files to find in the `self.raw_dir` folder in order to skip the download.

property processed_file_names(*self*)
The name of the files to find in the `self.processed_dir` folder in order to skip the processing.

abstract download(*self*)
Downloads the dataset to the `self.raw_dir` folder.

abstract process(*self*)
Processes the dataset to the `self.processed_dir` folder.

abstract __len__(*self*)
The number of examples in the dataset.

abstract get(*self*, *idx*)
Gets the data object at index `idx`.

property num_features(*self*)
Returns the number of features per node in the graph.

property raw_paths(*self*)
The filepaths to find in order to skip the download.

property processed_paths(*self*)
The filepaths to find in the `self.processed_dir` folder in order to skip the processing.

_download(*self*)

_process(*self*)

__getitem__(*self*, *idx*)
Gets the data object at index `idx` and transforms it (in case a `self.transform` is given).

__repr__(*self*)

data.download

Module Contents

Functions

download_url(url, folder, name=None, log=True)	Downloads the content of an URL to a specific folder.

data.download.**download_url**(*url*, *folder*, *name=None*, *log=True*)

Downloads the content of an URL to a specific folder.

Args: url (string): The url. folder (string): The folder. log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.extract

Module Contents

Functions

maybe_log(path, log=True)	
extract_tar(path, folder, mode='r:gz', log=True)	Extracts a tar archive to a specific folder.
extract_zip(path, folder, log=True)	Extracts a zip archive to a specific folder.
extract_bz2(path, folder, log=True)	
extract_gz(path, folder, log=True)	

data.extract.**maybe_log**(*path*, *log=True*)

data.extract.**extract_tar**(*path*, *folder*, *mode='r:gz'*, *log=True*)
Extracts a tar archive to a specific folder.

Args: path (string): The path to the tar archive. folder (string): The folder. mode (string, optional): The compression mode. (default: `"r:gz"`) log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.extract.**extract_zip**(*path*, *folder*, *log=True*)
Extracts a zip archive to a specific folder.

Args: path (string): The path to the tar archive. folder (string): The folder. log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.extract.**extract_bz2**(*path*, *folder*, *log=True*)

extract_gz(path, folder, log=True)	

class data.**Data**(*x=None*, *edge_index=None*, *edge_attr=None*, *y=None*, *pos=None*)

Bases: object

A plain old python object modeling a single graph with various (optional) attributes:

Args:

**x (Tensor, optional): Node feature matrix with shape :obj:`[num_nodes,** num_node_features]`. (default: None)

edge_index (LongTensor, optional): Graph connectivity in COO format with shape [2, num_edges]. (default: None)

edge_attr (Tensor, optional): Edge feature matrix with shape [num_edges, num_edge_features]. (default: None)

y (Tensor, optional): Graph or node targets with arbitrary shape. (default: None)

pos (Tensor, optional): Node position matrix with shape [num_nodes, num_dimensions]. (default: None)

The data object is not restricted to these attributes and can be extented by any other additional data.

static from_dict(*dictionary*)

Creates a data object from a python dictionary.

__getitem__(*self*, *key*)

Gets the data of the attribute key.

__setitem__(*self*, *key*, *value*)

Sets the attribute key to value.

property keys(*self*)

Returns all names of graph attributes.

__len__(*self*)
Returns the number of all present attributes.

__contains__(*self*, *key*)
Returns `True`, if the attribute `key` is present in the data.

__iter__(*self*)
Iterates over all present attributes in the data, yielding their attribute names and content.

__call__(*self*, **keys*)
Iterates over all attributes `*keys` in the data, yielding their attribute names and content. If `*keys` is not given this method will iterative over all present attributes.

cat_dim(*self*, *key*, *value*)
Returns the dimension in which the attribute `key` with content `value` gets concatenated when creating batches.

Note: This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

__inc__(*self*, *key*, *value*)
"Returns the incremental count to cumulatively increase the value of the next attribute of `key` when creating batches.

Note: This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

---

property num_edges(*self*)
Returns the number of edges in the graph.

property num_features(*self*)
Returns the number of features per node in the graph.

property num_nodes(*self*)

is_coalesced(*self*)
Returns `True`, if edge indices are ordered and do not contain duplicate entries.

apply(*self*, *func*, **keys*)
Applies the function `func` to all attributes `*keys`. If `*keys` is not given, `func` is applied to all present attributes.

contiguous(*self*, **keys*)
Ensures a contiguous memory layout for all attributes `*keys`. If `*keys` is not given, all present attributes are ensured to have a contiguous memory layout.

to(*self*, *device*, **keys*)
Performs tensor dtype and/or device conversion to all attributes `*keys`. If `*keys` is not given, the conversion is applied to all present attributes.

cuda(*self*, **keys*)

clone(*self*)

__repr__(*self*)
Return repr(self).

class data.**Batch**(*batch=None*, ***kwargs*)
Bases: `cogdl.data.Data`

A plain old python object modeling a batch of graphs as one big (dicconnected) graph. With `cogdl.data.Data` being the base class, all its methods can also be used here. In addition, single graphs can be reconstructed via the assignment vector *`batch`*, which maps each node to its respective graph identifier.

static from_data_list(*data_list*, *follow_batch=[]*)
Constructs a batch object from a python list holding `torch_geometric.data.Data` objects. The assignment vector *`batch`* is created on the fly. Additionally, creates assignment batch vectors for each key in `follow_batch`.

cumsum(*self*, *key*, *item*)
If `True`, the attribute `key` with content `item` should be added up cumulatively before concatenated together.

Note: This method is for internal use only, and should only be overridden if the batch concatenation process is corrupted for a specific data attribute.

---

to_data_list(*self*)
Reconstructs the list of `torch_geometric.data.Data` objects from the batch object. The batch object must have been created via *`from_data_list()`* in order to be able reconstruct the initial objects.

property num_graphs(*self*)
Returns the number of graphs in the batch.

class data.**Dataset**(*root*, *transform=None*, *pre_transform=None*, *pre_filter=None*)
Bases: `torch.utils.data.Dataset`

Dataset base class for creating graph datasets. See here for the accompanying tutorial.

Args: root (string): Root directory where the dataset should be saved. transform (callable, optional): A function/transform that takes in an

`cogdl.data.Data` object and returns a transformed version. The data object will be transformed before every access. (default: `None`)

pre_transform (callable, optional): A function/transform that takes in an `cogdl.data.Data` object and returns a transformed version. The data object will be transformed before being saved to disk. (default: `None`)

pre_filter (callable, optional): A function that takes in an `cogdl.data.Data` object and returns a boolean value, indicating whether the data object should be included in the final dataset. (default: `None`)

property raw_file_names(*self*)
The name of the files to find in the `self.raw_dir` folder in order to skip the download.

property processed_file_names(*self*)
The name of the files to find in the `self.processed_dir` folder in order to skip the processing.

abstract download(*self*)
Downloads the dataset to the `self.raw_dir` folder.

abstract process(*self*)
Processes the dataset to the `self.processed_dir` folder.

abstract __len__(*self*)
The number of examples in the dataset.

abstract get(*self*, *idx*)
Gets the data object at index `idx`.

property num_features(*self*)
Returns the number of features per node in the graph.

property raw_paths(*self*)
The filepaths to find in order to skip the download.

property processed_paths(*self*)
The filepaths to find in the `self.processed_dir` folder in order to skip the processing.

_download(*self*)

_process(*self*)

__getitem__(*self*, *idx*)
Gets the data object at index `idx` and transforms it (in case a `self.transform` is given).

__repr__(*self*)

class data.**DataLoader**(*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a mini-batch.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

class data.**DataListLoader**(*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a python list.

Note: This data loader should be used for multi-gpu support via `cogdl.nn.DataParallel`.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

class data.**DenseDataLoader**(*dataset*, *batch_size=1*, *shuffle=True*, ***kwargs*)
Bases: `torch.utils.data.DataLoader`

Data loader which merges data objects from a `cogdl.data.dataset` to a mini-batch.

Note: To make use of this data loader, all graphs in the dataset needs to have the same shape for each its attributes. Therefore, this data loader should only be used when working with *dense* adjacency matrices.

Args: dataset (Dataset): The dataset from which to load the data. batch_size (int, optional): How may samples per batch to load.

(default: `1`)

shuffle (bool, optional): If set to `True`, the data will be reshuffled at every epoch (default: `True`)

data.**download_url**(*url*, *folder*, *name=None*, *log=True*)
Downloads the content of an URL to a specific folder.

Args: url (string): The url. folder (string): The folder. log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.**extract_tar**(*path*, *folder*, *mode='r:gz'*, *log=True*)
Extracts a tar archive to a specific folder.

Args: path (string): The path to the tar archive. folder (string): The folder. mode (string, optional): The compression mode. (default: `"r:gz"`) log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.**extract_zip**(*path*, *folder*, *log=True*)
Extracts a zip archive to a specific folder.

Args: path (string): The path to the tar archive. folder (string): The folder. log (bool, optional): If `False`, will not print anything to the

console. (default: `True`)

data.**extract_bz2**(*path*, *folder*, *log=True*)

Bases: *datasets.gatne.GatneDataset*

The network datasets "Amazon", "Twitter" and "YouTube" from the "Representation Learning for Attributed Multiplex Heterogeneous Network" paper.

Args: root (string): Root directory where the dataset should be saved. name (string): The name of the dataset ("Amazon",

"Twitter", "YouTube").

class datasets.gatne.**TwitterDataset**
Bases: *datasets.gatne.GatneDataset*

The network datasets "Amazon", "Twitter" and "YouTube" from the "Representation Learning for Attributed Multiplex Heterogeneous Network" paper.

Args: root (string): Root directory where the dataset should be saved. name (string): The name of the dataset ("Amazon",

"Twitter", "YouTube").

class datasets.gatne.**YouTubeDataset**
Bases: *datasets.gatne.GatneDataset*

The network datasets "Amazon", "Twitter" and "YouTube" from the "Representation Learning for Attributed Multiplex Heterogeneous Network" paper.

Args: root (string): Root directory where the dataset should be saved. name (string): The name of the dataset ("Amazon",

"Twitter", "YouTube").

Submodules

models.emb.deepwalk

Module Contents

Classes

DeepWalk	The DeepWalk model from the `"DeepWalk: Online Learning of Social Representations"

class models.emb.deepwalk.**DeepWalk**(*dimension*, *walk_length*, *walk_num*, *window_size*, *worker*, *iteration*)

Bases: *models.BaseModel*

The DeepWalk model from the "DeepWalk: Online Learning of Social Representations" paper

Args: hidden_size (int) : The dimension of node representation. walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. window_size (int) : The actual context size which is considered in language model. worker (int) : The number of workers for word2vec. iteration (int) : The number of training iteration in word2vec.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

_walk(*self*, *start_node*, *walk_length*)

_simulate_walks(*self*, *walk_length*, *num_walks*)

models.emb.dgk

Classes

DeepGraphKernel	The Hin2vec model from the `"Deep Graph Kernels"

class models.emb.dgk.**DeepGraphKernel**(*hidden_dim*, *min_count*, *window_size*, *sampling_rate*, *rounds*, *epoch*, *alpha*, *n_workers=4*)

Bases: *models.BaseModel*

The Hin2vec model from the "Deep Graph Kernels" paper.

Args: hidden_size (int) : The dimension of node representation. min_count (int) : Parameter in word2vec. window (int) : The actual context size which is considered in language model. sampling_rate (float) : Parameter in word2vec. iteration (int) : The number of iteration in WL method. epoch (int) : The number of training iteration. alpha (float) : The learning rate of word2vec.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

static feature_extractor(*data*, *rounds*, *name*)

static wl_iterations(*graph*, *features*, *rounds*)

forward(*self*, *graphs*, ***kwargs*)

save_embedding(*self*, *output_path*)

models.emb.dngr

Classes

DNGR_layer	
DNGR	The DNGR model from the `"Deep Neural Networks for Learning Graph Representations"

class models.emb.dngr.**DNGR_layer**(*num_node*, *hidden_size1*, *hidden_size2*)
Bases: torch.nn.Module

forward(*self*, *x*)

class models.emb.dngr.**DNGR**(*hidden_size1*, *hidden_size2*, *noise*, *alpha*, *step*, *max_epoch*, *lr*, *cpu*)
Bases: *models.BaseModel*

The DNGR model from the "Deep Neural Networks for Learning Graph Representations" paper

Args: hidden_size1 (int) : The size of the first hidden layer. hidden_size2 (int) : The size of the second hidden layer. noise (float) : Denoise rate of DAE. alpha (float) : Parameter in DNGR. step (int) : The max step in random surfing. max_epoch (int) : The max epoches in training step. lr (float) : Learning rate in DNGR.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

class models.emb.gatne.**GATNE**(*dimension*, *walk_length*, *walk_num*, *window_size*, *worker*, *epoch*, *batch_size*, *edge_dim*, *att_dim*, *negative_samples*, *neighbor_samples*, *schema*)

Bases: *models.BaseModel*

The GATNE model from the "Representation Learning for Attributed Multiplex Heterogeneous Network" paper

Args: walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. window_size (int) : The actual context size which is considered in language model. worker (int) : The number of workers for word2vec. epoch (int) : The number of training epochs. batch_size (int) : The size of each training batch. edge_dim (int) : Number of edge embedding dimensions. att_dim (int) : Number of attention dimensions. negative_samples (int) : Negative samples for optimization. neighbor_samples (int) : Neighbor samples for aggregation schema (str) : The metapath schema used in model. Metapaths are splited with ",", while each node type are connected with "-" in each metapath. For example:"0-1-0,0-1-2-1-0"

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *network_data*)

class models.emb.gatne.**GATNEModel**(*num_nodes*, *embedding_size*, *embedding_u_size*, *edge_type_count*, *dim_a*)

Bases: torch.nn.Module

models.emb.graph2vec

Module Contents

Classes

Graph2Vec	The Graph2Vec model from the `"graph2vec: Learning Distributed Representations of Graphs"

class models.emb.graph2vec.**Graph2Vec**(*dimension*, *min_count*, *window_size*, *dm*, *sampling_rate*, *rounds*, *epoch*, *lr*, *worker=4*)

Bases: *models.BaseModel*

The Graph2Vec model from the "graph2vec: Learning Distributed Representations of Graphs" paper

Args: hidden_size (int) : The dimension of node representation. min_count (int) : Parameter in doc2vec. window_size (int) : The actual context size which is considered in language model. sampling_rate (float) : Parameter in doc2vec. dm (int) : Parameter in doc2vec. iteration (int) : The number of iteration in WL method. epoch (int) : The max epoches in training step. lr (float) : Learning rate in doc2vec.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

static feature_extractor(*data*, *rounds*, *name*)

static wl_iterations(*graph*, *features*, *rounds*)

forward(*self*, *graphs*, ***kwargs*)

save_embedding(*self*, *output_path*)

models.emb.grarep

Module Contents

Classes

GraRep	The GraRep model from the `"Grarep: Learning graph representations with global structural information"

class models.emb.grarep.**GraRep**(*dimension*, *step*)
Bases: *models.BaseModel*

The GraRep model from the "Grarep: Learning graph representations with global structural information" paper.

Args: hidden_size (int) : The dimension of node representation. step (int) : The maximum order of transitition probability.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

_get_embedding(*self*, *matrix*, *dimension*)

models.emb.hin2vec

Module Contents

Classes

Hin2vec_layer	
RWgraph	
Hin2vec	The Hin2vec model from the `"HIN2Vec: Explore Meta-paths in Heterogeneous Information Networks for Representation Learning"

class models.emb.hin2vec.**Hin2vec_layer**(*num_node*, *num_relation*, *hidden_size*, *cpu*)
Bases: torch.nn.Module

regulartion(*self*, *embr*)

forward(*self*, *x*, *y*, *r*, *l*)

get_emb(*self*)

class models.emb.hin2vec.**RWgraph**(*nx_G*, *node_type=None*)

_simulate_walks(*self*, *walk_length*, *num_walks*)

data_preparation(*self*, *walks*, *hop*, *negative*)

class models.emb.hin2vec.**Hin2vec**(*hidden_dim*, *walk_length*, *walk_num*, *batch_size*, *hop*, *negative*, *epoches*, *lr*, *cpu=True*)

Bases: *models.BaseModel*

The Hin2vec model from the "HIN2Vec: Explore Meta-paths in Heterogeneous Information Networks for Representation Learning" paper.

Args: hidden_size (int) : The dimension of node representation. walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. batch_size (int) : The batch size of training in Hin2vec. hop (int) : The number of hop to construct training samples in Hin2vec. negative (int) : The number of nagative samples for each meta2path pair. epoches (int) : The number of training iteration. lr (float) : The initial learning rate of SGD. cpu (bool) : Use CPU or GPU to train hin2vec.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*, *node_type*)

models.emb.hope

Module Contents

Classes

HOPE	The HOPE model from the `"Grarep: Asymmetric transitivity preserving graph embedding"

class models.emb.hope.**HOPE**(*dimension*, *beta*)

Bases: *models.BaseModel*

The HOPE model from the "Grarep: Asymmetric transitivity preserving graph embedding" paper.

Args: hidden_size (int) : The dimension of node representation. beta (float) : Parameter in katz decomposition.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)
The author claim that Katz has superior performance in related tasks S_katz = (M_g)^-1 * M_l = (I - beta*A)^-1 * beta*A = (I - beta*A)^-1 * (I - (I -beta*A)) = (I - beta*A)^-1 - I

_get_embedding(*self*, *matrix*, *dimension*)

models.emb.line

Module Contents

Classes

LINE	The LINE model from the `"Line: Large-scale information network embedding"

class models.emb.line.**LINE**(*dimension*, *walk_length*, *walk_num*, *negative*, *batch_size*, *alpha*, *order*)

Bases: *models.BaseModel*

The LINE model from the "Line: Large-scale information network embedding" paper.

Args: hidden_size (int) : The dimension of node representation. walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. negative (int) : The number of nagative samples for each edge. batch_size (int) : The batch size of training in LINE. alpha (float) : The initial learning rate of SGD. order (int) : 1 represents perserving 1-st order proximity, 2 represents 2-nd, while 3 means both of them (each of them having dimension/2 node representation).

static add_args(*parser*)

Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)

Build a new model instance.

train(*self*, *G*)

_update(*self*, *vec_u*, *vec_v*, *vec_error*, *label*)

_train_line(*self*, *order*)

models.emb.metapath2vec

Module Contents

Classes

Metapath2vec	The Metapath2vec model from the `"metapath2vec: Scalable Representation

class models.emb.metapath2vec.**Metapath2vec**(*dimension*, *walk_length*, *walk_num*, *window_size*, *worker*, *iteration*, *schema*)

Bases: *models.BaseModel*

The Metapath2vec model from the "metapath2vec: Scalable Representation Learning for Heterogeneous Networks" paper

Args: hidden_size (int) : The dimension of node representation. walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. window_size (int) : The actual context size which is considered in language model. worker (int) : The number of workers for word2vec. iteration (int) : The number of training iteration in word2vec. schema (str) : The metapath schema used in model. Metapaths are splited with ",", while each node type are connected with "-" in each metapath. For

example:"0-1-0,0-2-0,1-0-2-0-1".

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*, *node_type*)

_walk(*self*, *start_node*, *walk_length*, *schema=None*)

_simulate_walks(*self*, *walk_length*, *num_walks*, *schema='No'*)

models.emb.netmf

Module Contents

Classes

NetMF	The NetMF model from the `"Network Embedding as Matrix Factorization: Unifying DeepWalk, LINE, PTE, and node2vec"

class models.emb.netmf.**NetMF**(*dimension*, *window_size*, *rank*, *negative*, *is_large=False*)
Bases: *models.BaseModel*

The NetMF model from the "Network Embedding as Matrix Factorization: Unifying DeepWalk, LINE, PTE, and node2vec" paper.

Args: hidden_size (int) : The dimension of node representation. window_size (int) : The actual context size which is considered in language model. rank (int) : The rank in approximate normalized laplacian. negative (int) : The number of nagative samples in negative sampling. is-large (bool) : When window size is large, use approximated deepwalk matrix to decompose.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

_compute_deepwalk_matrix(*self*, *A*, *window*, *b*)

_approximate_normalized_laplacian(*self*, *A*, *rank*, *which='LA'*)

_deepwalk_filter(*self*, *evals*, *window*)

_approximate_deepwalk_matrix(*self*, *evals*, *D_rt_invU*, *window*, *vol*, *b*)

models.emb.netsmf

Module Contents

Classes

NetSMF	The NetSMF model from the `"NetSMF: Large-Scale Network Embedding as Sparse Matrix Factorization"

class models.emb.netsmf.**NetSMF**(*dimension*, *window_size*, *negative*, *num_round*, *worker*)

Bases: *models.BaseModel*

The NetSMF model from the "NetSMF: Large-Scale Network Embedding as Sparse Matrix Factorization" paper.

Args: hidden_size (int) : The dimension of node representation. window_size (int) : The actual context size which is considered in language model. negative (int) : The number of nagative samples in negative sampling. num_round (int) : The number of round in NetSMF. worker (int) : The number of workers for NetSMF.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

models.emb.pte

Module Contents

Classes

PTE	The PTE model from the `"PTE: Predictive Text Embedding through Large-scale Heterogeneous Text Networks"

class models.emb.pte.**PTE**(*dimension*, *walk_length*, *walk_num*, *negative*, *batch_size*, *alpha*)

Bases: *models.BaseModel*

The PTE model from the "PTE: Predictive Text Embedding through Large-scale Heterogeneous Text Networks" paper.

Args: hidden_size (int) : The dimension of node representation. walk_length (int) : The walk length. walk_num (int) : The number of walks to sample for each node. negative (int) : The number of nagative samples for each edge. batch_size (int) : The batch size of training in PTE. alpha (float) : The initial learning rate of SGD.

static add_args(*parser*)

Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)

Build a new model instance.

train(*self*, *G*, *node_type*)

_update(*self*, *vec_u*, *vec_v*, *vec_error*, *label*)

_train_line(*self*)

models.emb.sdne

Module Contents

Classes

SDNE_layer	
SDNE	The SDNE model from the `"Structural Deep Network Embedding"

class models.emb.sdne.**SDNE_layer**(*num_node*, *hidden_size1*, *hidden_size2*, *droput*, *alpha*, *beta*, *nu1*, *nu2*)

Bases: torch.nn.Module

forward(*self*, *adj_mat*, *l_mat*)

get_emb(*self*, *adj*)

class models.emb.sdne.**SDNE**(*hidden_size1*, *hidden_size2*, *droput*, *alpha*, *beta*, *nu1*, *nu2*, *max_epoch*, *lr*, *cpu*)

Bases: *models.BaseModel*

The SDNE model from the "Structural Deep Network Embedding" paper

Args: hidden_size1 (int) : The size of the first hidden layer. hidden_size2 (int) : The size of the second hidden layer. droput (float) : Droput rate. alpha (float) : Trade-off parameter between 1-st and 2-nd order objective function in SDNE. beta (float) : Parameter of 2-nd order objective function in SDNE. nu1 (float) : Parameter of l1 normlization in SDNE. nu2 (float) : Parameter of l2 normlization in SDNE. max_epoch (int) : The max epoches in training step. lr (float) : Learning rate in SDNE. cpu (bool) : Use CPU or GPU to train hin2vec.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

models.emb.spectral

Module Contents

Classes

Spectral	The Spectral clustering model from the `"Leveraging social media networks for classication"

class models.emb.spectral.**Spectral**(*dimension*)
Bases: *models.BaseModel*

The Spectral clustering model from the "Leveraging social media networks for classication" paper

Args: hidden_size (int) : The dimension of node representation.

static add_args(*parser*)
Add model-specific arguments to the parser.

classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

train(*self*, *G*)

Bases: *models.BaseModel*

DIFFPOOL from paper Hierarchical Graph Representation Learning with Differentiable Pooling.

in_feats [int] Size of each input sample.

hidden_dim [int] Size of hidden layer dimension of GNN.

embed_dim [int] Size of embeded node feature, output size of GNN.

num_classes [int] Number of target classes.

num_layers [int] Number of GNN layers.

num_pool_layers [int] Number of pooling.

assign_dim [int] Embedding size after the first pooling.

pooling_ratio [float] Size of each poolling ratio.

batch_size [int] Size of each mini-batch.

dropout [float, optional] Size of dropout, default: *0.5*.

no_link_pred [bool, optional] If True, use link prediction loss, default: *True*.

6.7.2 Submodules

models.base_model

Module Contents

Classes

BaseModel	

class models.base_model.**BaseModel**

Bases: torch.nn.Module

static add_args(*parser*)
Add model-specific arguments to the parser.

abstract classmethod build_model_from_args(*cls*, *args*)
Build a new model instance.

6.7.3 Package Contents

Classes

BaseModel	

Functions

register_model(name)	New model types can be added to cogdl with the *register_model()*
alias_setup(probs)	Compute utility lists for non-uniform sampling from discrete distributions.
alias_draw(J, q)	Draw sample from a non-uniform discrete distribution using alias sampling.
build_model(args)	

class models.**BaseModel**

Bases: torch.nn.Module

static add_args(*parser*)

Add model-specific arguments to the parser.

abstract classmethod build_model_from_args(*cls*, *args*)

Build a new model instance.

models.**pyg = False**

models.**dgl_import = False**

models.**MODEL_REGISTRY**

models.**register_model**(*name*)

New model types can be added to cogdl with the *register_model()* function decorator.

For example:

```
@register_model('gat')
class GAT(BaseModel):
    (...)
```

Args: name (str): the name of the model

models.**alias_setup**(*probs*)

Compute utility lists for non-uniform sampling from discrete distributions. Refer to https://hips.seas.harvard.edu/blog/2013/03/03/the-alias-method-efficient-sampling-with-many-discrete-outcomes/ for details

models.**alias_draw**(*J*, *q*)

Draw sample from a non-uniform discrete distribution using alias sampling.

models.**model_name**

models.**build_model**(*args*)
